## NEW ZEOLITE SSZ-31

BACKGROUND OF THE INVENTION

01  
02  
03  
04  
05 Natural and synthetic zeolitic crystalline metalosilicates  
06 are useful as catalysts and adsorbents. Metalosilicate  
07 molecular sieves are zeolites with a silicate lattice  
08 wherein a metal can be substituted into the tetrahedral  
09 positions of the silicate framework. These metals include  
10 aluminum, gallium iron and mixtures thereof. These metalo-  
11 silicates have distinct crystal structures which are  
12 demonstrated by X-ray diffraction. The crystal structure  
13 defines cavities and pores which are characteristic of the  
14 different species. The adsorptive and catalytic properties  
15 of each crystalline metalosilicate are determined in part by  
16 the dimensions of its pores and cavities. Thus, the utility  
17 of a particular zeolite in a particular application depends  
18 at least partly on its crystal structure.

19  
20 Because of their unique molecular sieving characteristics,  
21 as well as their catalytic properties, some crystalline  
22 metalosilicates are especially useful in such applications  
23 as gas drying and separation and hydrocarbon conversion.  
24 Although many different crystalline aluminosilicates,  
25 borosilicate and silicates have been disclosed, there is a  
26 continuing need for new zeolites and silicates with  
27 desirable properties for gas separation and drying,  
28 hydrocarbon and chemical conversions, and other  
29 applications.

30  
31 Crystalline aluminosilicates are usually prepared from  
32 aqueous reaction mixtures containing alkali or alkaline  
33 earth metal oxides, silica, and alumina. "Nitrogenous  
34 zeolites" have been prepared from reaction mixtures

-2-

01 containing an organic templating agent, usually a nitrogen-  
02 containing organic cation. By varying the synthesis  
03 conditions and the composition of the reaction mixture,  
04 different zeolites can be formed using the same templating  
05 agent. Use of N,N,N-trimethyl cyclopentylammonium iodide in  
06 the preparation of Zeolite SSZ-15 molecular sieve is dis-  
07 closed in U.S. Patent No. 4,610,854; use of 1-azoniaspiro  
08 [4.4] nonyl bromide and N,N,N-trimethyl neopentylammonium  
09 iodide in the preparation of a molecular sieve termed  
10 "Losod" is disclosed in Helv. Chim. Acta (1974); Vol. 57,  
11 p. 1533 (W. Sieber and W. M. Meier); use of quinuclidinium  
12 compounds to prepare a zeolite termed "NU-3" is disclosed in  
13 European Patent Publication No. 40016; use of  
14 1,4-di(1-azoniabicyclo[2.2.2.]octane) lower alkyl compounds  
15 in the preparation of Zeolite SSZ-16 molecular sieve is  
16 disclosed in U.S. Patent No. 4,508,837; use of  
17 N,N,N-trialkyl-1-adamantamine in the preparation of Zeolite  
18 SSZ-13 molecular sieve is disclosed in U.S. Patent No.  
19 4,544,538, and for SSZ-24 in U.S. Patent No. 4,665,110.

20  
21 Synthetic zeolitic crystalline borosilicates are useful as  
22 catalysts. Methods for preparing high silica content zeo-  
23 lites that contain framework boron are known and disclosed  
24 in U.S. Patent No. 4,269,813. The amount of boron contained  
25 in the zeolite may be made to vary by incorporating  
26 different amounts of borate ion in the zeolite-forming  
27 solution. In some instances, it is necessary to provide  
28 boron as a pre-formed borosilicate.

29

30 The present invention relates to a novel family of stable  
31 synthetic crystalline materials identified as SSZ-31 and  
32 having a specified X-ray diffraction pattern, and also to  
33 the preparation and use of such materials.

34

-3-

SUMMARY OF THE INVENTION

01

02

03 We have prepared a family of crystalline metallosilicate  
04 molecular sieves with unique properties, referred to herein  
05 as "Zeolite SSZ-31" or simply "SSZ-31", and have found  
06 highly effective methods for preparing SSZ-31.  
07

08 Metallosilicate molecular sieves are zeolites with a  
09 silicate lattice wherein a metal can be substituted into the  
10 tetrahedral positions of the silicate framework. These  
11 metals include aluminum, gallium, iron, boron, titanium and  
12 mixtures thereof.  
13

14 The zeolite has compositions as synthesized and in the  
15 anhydrous state, in terms of oxides as follows:  $(1.0 \text{ to } 5)Q_2O:(0.1 \text{ to } 2.0)M_2O:W_2O_3(\text{greater than } 50)YO_2$ , wherein M is  
16 an alkali metal cation, W is selected from boron, Y is  
17 selected from silicon, germanium and mixtures thereof, and Q  
18 is a cyclic quaternary ammonium ion; and  $(0.1 \text{ to } 10)Q'_2O:(0.1 \text{ to } 5.0)M_2O:W'_2O_3(\text{greater than } 100)Y'O_2$ , wherein  
19 M is an alkali metal cation, W' is selected from aluminum,  
20 gallium, iron, and mixtures thereof, Y' is selected from  
21 silicon, germanium and mixtures thereof and Q' is a  
22 tricyclodecane quaternary ammonium ion.  
23  
24  
25

26 SSZ-31 zeolites may be prepared using various methods. The  
27 method for preparing SSZ-31 with a  $YO_2:W_2O_3$  mole ratio  
28 greater than 50:1 comprises preparing an aqueous mixture  
29 containing sources of a quaternary ammonium ion, an alkali  
30 oxide, an oxide selected from boron as a borosilicate, not  
31 simply a boron oxide, and an oxide selected from silicon  
32 oxide, germanium oxide, and mixtures thereof, and having a  
33 composition, in terms of mole ratios of oxides, falling  
34 within the following ranges:  $YO_2/W_2O_3$ , greater than 50:1;

-4-

01 wherein Y is selected from silicon, germanium, and mixtures  
02 thereof, W is selected from boron, and Q is a quaternary  
03 ammonium ion; maintaining the mixture at a temperature of at  
04 least 100°C until the crystals of said zeolite are formed;  
05 and recovering said crystals.

06

07 A preferred borosilicate source is boron beta zeolite  
08 described in commonly assigned co-pending application U.S.  
09 Serial No. 377,359 filed July 7, 1989, and entitled  
10 "Low-Aluminum Boron Beta Zeolite".

11

12 The method for preparing SSZ-31 with a  $Y'O_2:W'_2O_3$  mole ratio  
13 greater than 100:1 comprises preparing an aqueous mixture  
14 containing sources of a tricyclodecane quaternary ammonium  
15 ion, an oxide selected from aluminum oxide, gallium oxide,  
16 iron oxide, and mixtures thereof, and an oxide selected from  
17 silicon oxide, germanium oxide, and mixtures thereof, and  
18 having a composition, in terms of mole ratios of oxides,  
19 falling within the following ranges:  $Y'O_2/W'_2O_3$ , 100:1 to  
20 infinity (essentially pure  $Y'O_2$ ); wherein Y' is selected  
21 from silicon, germanium, and mixtures thereof, W' is  
22 selected from aluminum, gallium, iron, and mixtures thereof,  
23 and Q' is a tricyclodecane quaternary ammonium ion;  
24 maintaining the mixture at a temperature of at least 100°C  
25 until the crystals of said zeolite are formed; and  
26 recovering said crystals.

27

28 We have found that the SSZ-31 zeolite has unexpectedly  
29 outstanding hydrocarbon conversion properties, particularly  
30 including hydrocracking, chemicals production, reforming and  
31 catalytic cracking.

32

33

34

-5-

DETAILED DESCRIPTION OF THE INVENTION

SSZ-31 zeolites, as synthesized, have a crystalline structure whose X-ray powder diffraction pattern shows the following characteristic lines:

TABLE 1

<u>2 <math>\theta</math></u>	<u>d/n</u>	<u>I/I<sub>0</sub></u>
6.10	14.49	6
7.38	11.98	30
8.18	10.81	11
20.30	4.37	15
21.12	4.21	69
22.25	3.99	100
24.73	3.60	23
30.90	2.89	11

Typical SSZ-31 borosilicate zeolites have the X-ray diffraction patterns of Table 6 below.

The X-ray powder diffraction patterns were determined by standard techniques. The radiation was the K-alpha/doublet of copper and a scintillation counter spectrometer with a strip chart pen recorder was used. The peak heights I and the positions, as a function of 2  $\theta$  where  $\theta$  is the Bragg angle, were read from the spectrometer chart. From these measured values, the relative intensities,  $100I/I_0$ , where  $I_0$  is the intensity of the strongest line or peak, and d, the interplanar spacing in Angstroms corresponding to the recorded lines, can be calculated. The X-ray diffraction pattern of Table 1 is characteristic of SSZ-31 zeolites. The zeolite produced by exchanging the metal or other cations present in the zeolite with various other cations

-6-

01 yields substantially the same diffraction pattern although  
 02 there can be minor shifts in interplanar spacing and minor  
 03 variations in relative intensity. Minor variations in the  
 04 diffraction pattern can also result from variations in the  
 05 organic compound used in the preparation and from variations  
 06 in the silica-to-alumina mole ratio from sample to sample.  
 07 Calcination can also cause minor shifts in the X-ray  
 08 diffraction pattern. Notwithstanding these minor  
 09 perturbations, the basic crystal lattice structure remains  
 10 unchanged.

11

12 Various methods can be used to prepare the SSZ-31 zeolite.  
 13 SSZ-31 zeolites with a  $\text{YO}_2:\text{W}_2\text{O}_3$  mole ratio greater than 50:1  
 14 can be suitably prepared from an aqueous solution containing  
 15 sources of an alkali metal oxide, a quaternary ammonium ion,  
 16 borosilicate, and an oxide of silicon or germanium, or  
 17 mixture of the two. The reaction mixture should have a  
 18 composition in terms of mole ratios falling within the  
 19 following ranges:

20

	<u>Broad</u>	<u>Preferred</u>
23 $\text{YO}_2/\text{W}_2\text{O}_3$	30-∞	50-∞
24 $\text{OH}/\text{YO}_2$	0.10-0.50	0.15-0.25
25 $\text{Q}/\text{YO}_2$	0.05-0.50	0.10-0.25
26 $\text{M}^+/\text{YO}_2$	0.05-0.30	0.05-0.15
27 $\text{H}_2\text{O}/\text{YO}_2$	15-300	25-60
28 $\text{Q}/\text{Q}+\text{M}^+$	0.30-0.70	0.40-0.60

29

30 wherein Q is a quaternary ammonium ion, Y is silicon,  
 31 germanium or both, and W is boron. M is an alkali metal,  
 32 preferably sodium. The organic compound which acts as a  
 33

34

-7-

01 source of the quaternary ammonium ion employed can provide  
 02 hydroxide ion. W is shown as boron, but is provided to the  
 03 reaction as borosilicate. The quaternary ammonium compounds  
 04 which may be used to prepare these SSZ-31 zeolites are shown  
 05 in Table 2 as Templates B-F. Examples 12, 13, 14, 15 and 16  
 06 show methods of preparing the Templates B-F in Table 2.

07

08 When using the quaternary ammonium hydroxide compound as a  
 09 template, it has also been found that purer forms of SSZ-31  
 10 are prepared when there is an excess of compound present  
 11 relative to the amount of alkali metal hydroxide.

01 The reaction mixture is prepared using standard zeolitic  
02 preparation techniques. Sources of borosilicates for the  
03 reaction mixture include borosilicate glasses and most  
04 particularly, other reactive borosilicate molecular sieves.  
05 One very reactive source is boron beta zeolite described in  
06 commonly assigned co-pending application U.S. Serial  
07 No. 377,359, filed July 7, 1989, and entitled "Low-Aluminum  
08 Boron Beta Zeolite". Typical sources of silicon oxide  
09 include silicates, silica hydrogel, silicic acid, colloidal  
10 silica, fumed silica, tetra-alkyl orthosilicates, and silica  
11 hydroxides.

12  
13 The reaction mixture is maintained at an elevated  
14 temperature until the crystals of the zeolite are formed.  
15 The temperatures during the hydrothermal crystallization  
16 step are typically maintained from about 120°C to about  
17 200°C, preferably from about 130°C to about 170°C and most  
18 preferably from about 135°C to about 165°C. The  
19 crystallization period is typically greater than one day and  
20 preferably from about three days to about seven days.

21  
22 The hydrothermal crystallization is conducted under pressure  
23 and usually in an autoclave so that the reaction mixture is  
24 subject to autogenous pressure. The reaction mixture can be  
25 stirred during crystallization.

26  
27 Once the zeolite crystals have formed, the solid product is  
28 separated from the reaction mixture by standard mechanical  
29 separation techniques such as filtration. The crystals are  
30 water-washed and then dried, e.g., at 90°C to 150°C from 8  
31 to 24 hours, to obtain the as synthesized, SSZ-31 zeolite  
32 crystals. The drying step can be performed at atmospheric  
33 or subatmospheric pressures.

34

-10-

01 During the hydrothermal crystallization step, the SSZ-31  
 02 crystals can be allowed to nucleate spontaneously from the  
 03 reaction mixture. The reaction mixture can also be seeded  
 04 with SSZ-31 crystals both to direct, and accelerate the  
 05 crystallization, as well as to minimize the formation of  
 06 undesired borosilicate contaminants.  
 07  
 08 SSZ-31 with a  $Y'O_2:W'_2O_3$  mole ratio greater than 100:1 can  
 09 can be suitably prepared from an aqueous solution containing  
 10 sources of an alkali metal oxide, a tricyclodecane  
 11 quaternary ammonium ion, an oxide of aluminum, gallium,  
 12 iron, or mixtures thereof, and an oxide of silicon or  
 13 germanium, or mixture of the two. The reaction mixture  
 14 should have a composition in terms of mole ratios falling  
 15 within the following ranges:

	<u>Broad</u>	<u>Preferred</u>
19 $Y'O_2/W'_2O_3$	100-∞	200-∞
20 $OH^-/Y'O_2$	0.10-0.60	0.20-0.50
21 $Q'/Y'O_2$	0.05-0.50	0.10-0.40
22 $M^+/Y'O_2$	0.05-0.30	0.05-0.15
23 $H_2O/Y'O_2$	10-300	25-60
24 $Q'/Q'+M^+$	0.30-0.80	0.40-0.75

25  
 26 wherein  $Q'$  is a tricyclodecane quaternary ammonium ion,  $Y'$   
 27 is silicon, germanium or both, and  $W'$  is aluminum, gallium,  
 28 iron, or mixtures thereof.  $M$  is an alkali metal, preferably  
 29 sodium or potassium. The organic tricyclodecane compound  
 30 which acts as a source of the quaternary ammonium ion  
 31 employed can provide hydroxide ion.

32  
 33 When using the quaternary ammonium hydroxide compound as a  
 34 template, it has also been found that purer forms of SSZ-31

-11-

01 are prepared when there is an excess of tricyclodecane  
 02 compound present relative to the amount of alkali metal  
 03 hydroxide and that when the  $\text{OH}^-/\text{SiO}_2$  molar ratio is greater  
 04 than 0.40, then  $\text{M}^+/\text{SiO}_2$  molar ratio should be less than  
 05 0.20.

06  
 07 The quaternary ammonium ion component Q, of the crystalli-  
 08 zation mixture, is derived from a [5.2.1.0] tricyclodecane  
 09 quaternary ammonium compound with the nitrogen at the eight  
 10 position of the ring system. Preferably, the quaternary  
 11 ammonium ion is derived from a compound of the Formula (1):

(1)

18  
 19 wherein each of  $R_1$ ,  $R_2$  and  $R_3$  independently is lower alkyl  
 20 and most preferably methyl; and  $A^-$  is an anion which is not  
 21 detrimental to the formation of the zeolite. A method of  
 22 making this template is described in Example 1.

23  
 24 The tricyclodecane quaternary ammonium compounds of the  
 25 Formula (1) above are prepared by methods known in the art.  
 26 For example, compounds of the Formula (1) wherein  $A^-$  is a  
 27 halide may be prepared by reacting an N,N-di(lower)alkyl-8-  
 28 amino tricyclo [5.2.1.0] decane compound of the Formula (2):

(2)

-12-

01 wherein each of  $R_1$  and  $R_2$  independently is lower alkyl, with  
02 a lower alkyl halide, in a solvent such as ethyl acetate.  
03 The halide anion may be ion exchanged to obtain other anions  
04 such as hydroxide, acetate, sulfate, carboxydate, and the  
05 like. The N,N-di(lower)alkyl-8-amino tricycle [5.2.1.0]  
06 decane of the Formula (2) above may be prepared by reacting  
07 8-ketotricyclo [5.2.1.0] decane with a lower dialkyl  
08 formamide in the presence of formic acid at a temperature in  
09 the range of 160°-195°C in a closed system. The reaction  
10 can be carried out for 10-50 hours, with the product  
11 recovered by partitioning between ether and a basic aqueous  
12 solution.

13  
14 By "lower alkyl" is meant alkyl of from about 1 to 3 carbon  
15 atoms.

16  
17  $A^\ominus$  is an anion which is not detrimental to the formation of  
18 the zeolite. Representative of the anions include halogen,  
19 e.g., fluoride, chloride, bromide and iodide, hydroxide,  
20 acetate, sulfate, carboxylate, etc. Hydroxide is the most  
21 preferred anion. It may be beneficial to ion-exchange, for  
22 example, the halide for hydroxide ion, thereby reducing or  
23 eliminating the alkali metal hydroxide quantity required.

24  
25 The reaction mixture is prepared using standard zeolitic  
26 preparation techniques. Typical sources of aluminum oxide  
27 for the reaction mixture include aluminates, alumina, other  
28 zeolites, and aluminum compounds such as  $AlCl_3$  and  
29  $Al_2(SO_4)_3$ , and colloidal dispersions of alumina and alumina  
30 on silica, such as the Nalco product 1SJ612. Typical  
31 sources of silicon oxide include silicates, silica hydrogel,  
32 silicic acid, colloidal silica, tetraalkyl orthosilicates,  
33 and silica hydroxides. Gallium, iron, and germanium can be  
34 added in forms corresponding to their aluminum and silicon

-13-

01 counterparts. Salts, particularly alkali metal halides such  
02 as sodium chloride, can be added to or formed in the  
03 reaction mixture. They are disclosed in the literature as  
04 aiding the crystallization of zeolites while preventing  
05 silica occlusion in the lattice.

06  
07 The reaction mixture is maintained at an elevated  
08 temperature until the crystals of the zeolite are formed.  
09 The temperatures during the hydrothermal crystallization  
10 step are typically maintained from about 140°C to about  
11 200°C, preferably from about 150°C to about 170°C, and most  
12 preferably from about 155°C to about 165°C. The crystalli-  
13 zation period is typically greater than 1 day and preferably  
14 from about 6 days to about 12 days.

15  
16 The hydrothermal crystallization is conducted under pressure  
17 and usually in an autoclave so that the reaction mixture is  
18 subject to autogenous pressure. The reaction mixture can be  
19 stirred during crystallization.

20  
21 Once the zeolite crystals have formed, the solid product is  
22 separated from the reaction mixture by standard mechanical  
23 separation techniques such as filtration. The crystals are  
24 waterwashed and then dried, e.g., at 90°C to 150°C for from  
25 8 to 24 hours, to obtain the as synthesized, SSZ-31 zeolite  
26 crystals. The drying step can be performed at atmospheric  
27 or subatmospheric pressures.

28  
29 During the hydrothermal crystallization step, the SSZ-31  
30 crystals can be allowed to nucleate spontaneously from the  
31 reaction mixture. The reaction mixture can also be seeded  
32 with SSZ-31 crystals both to direct, and accelerate the  
33 crystallization, as well as to minimize the formation of  
34 undesired aluminosilicate contaminants.

-14-

01 The synthetic SSZ-31 zeolites can be used as synthesized or  
02 can be thermally treated (calcined). Usually, it is  
03 desirable to remove the alkali metal cation by ion exchange  
04 and replace it with hydrogen, ammonium, or any desired metal  
05 ion. The zeolite can be leached with chelating agents,  
06 e.g., EDTA or dilute acid solutions, to increase the  
07 silica:alumina mole ratio. The zeolite can also be steamed;  
08 steaming helps stabilize the crystalline lattice to attack  
09 from acids. The zeolite can be used in intimate combination  
10 with hydrogenating components, such as tungsten, vanadium,  
11 molybdenum, rhenium, nickel, cobalt, chromium, manganese, or  
12 a noble metal, such as palladium or platinum, for those  
13 applications in which a hydrogenation-dehydrogenation  
14 function is desired. Typical replacing cations can include  
15 metal cations, e.g., rare earth, Group IIA and Group VIII  
16 metals, as well as their mixtures. Of the replacing  
17 metallic cations, cations of metals such as rare earth, Mn,  
18 Ca, Mg, Zn, Cd, Pt, Pd, Ni, Co, Ti, Al, Sn, Fe, and Co are  
19 particularly preferred.

20  
21 The hydrogen, ammonium, and metal components can be  
22 exchanged into the zeolite. The zeolite can also be  
23 impregnated with the metals, or, the metals can be  
24 physically intimately admixed with the zeolite using  
25 standard methods known to the art. And, some metals can be  
26 occluded in the crystal lattice by having the desired metals  
27 present as ions in the reaction mixture from which the  
28 SSZ-31 zeolite is prepared.

29  
30 Typical ion exchange techniques involve contacting the  
31 synthetic zeolite with a solution containing a salt of the  
32 desired replacing cation or cations. Although a wide  
33 variety of salts can be employed, chlorides and other

34

-15-

01 halides, nitrates, and sulfates are particularly preferred.  
02 Representative ion exchange techniques are disclosed in a  
03 wide variety of patents including U.S. Nos. 3,140,249;  
04 3,140,251; and 3,140,253. Ion exchange can take place  
05 either before or after the zeolite is calcined.

06  
07 Following contact with the salt solution of the desired  
08 replacing cation, the zeolite is typically washed with water  
09 and dried at temperatures ranging from 65°C to about 315°C.  
10 After washing, the zeolite can be calcined in air or inert  
11 gas at temperatures ranging from about 200°C to 820°C for  
12 periods of time ranging from 1 to 48 hours, or more, to  
13 produce a catalytically active product especially useful in  
14 hydrocarbon conversion processes.

15  
16 Regardless of the cations present in the synthesized form of  
17 the zeolite, the spatial arrangement of the atoms which form  
18 the basic crystal lattice of the zeolite remains essentially  
19 unchanged. The exchange of cations has little, if any,  
20 effect on the zeolite lattice structures.

21  
22 The SSZ-31 zeolites can be formed into a wide variety of  
23 physical shapes. Generally speaking, the zeolite can be in  
24 the form of a powder, a granule, or a molded product, such  
25 as extrudate having particle size sufficient to pass through  
26 a 2-mesh (Tyler) screen and be retained on a 400-mesh  
27 (Tyler) screen. In cases where the catalyst is molded, such  
28 as by extrusion with an organic binder, the aluminosilicate  
29 can be extruded before drying, or, dried or partially dried  
30 and then extruded. The zeolite can be composited with other  
31 materials resistant to the temperatures and other conditions  
32 employed in organic conversion processes. Such matrix  
33 materials include active and inactive materials and  
34 synthetic or naturally occurring zeolites as well as

-16-

01 inorganic materials such as clays, silica and metal oxides.  
02 The latter may occur naturally or may be in the form of  
03 gelatinous precipitates, sols, or gels, including mixtures  
04 of silica and metal oxides. Use of an active material in  
05 conjunction with the synthetic zeolite, i.e., combined with  
06 it, tends to improve the conversion and selectivity of the  
07 catalyst in certain organic conversion processes. Inactive  
08 materials can suitably serve as diluents to control the  
09 amount of conversion in a given process so that products can  
10 be obtained economically without using other means for  
11 controlling the rate of reaction. Frequently, zeolite  
12 materials have been incorporated into naturally occurring  
13 clays, e.g., bentonite and kaolin. These materials, i.e.,  
14 clays, oxides, etc., function, in part, as binders for the  
15 catalyst. It is desirable to provide a catalyst having good  
16 crush strength, because in petroleum refining the catalyst  
17 is often subjected to rough handling. This tends to break  
18 the catalyst down into powders which cause problems in  
19 processing.

20

21 Naturally occurring clays which can be composited with the  
22 synthetic zeolites of this invention include the  
23 montmorillonite and kaolin families, which families include  
24 the sub-bentonites and the kaolins commonly known as Dixie,  
25 McNamee, Georgia, and Florida clays or others in which the  
26 main mineral constituent is halloysite, kaolinite, dickite,  
27 nacrite, or anauxite. Fibrous clays such as sepiolite and  
28 attapulgite can also be used as supports. Such clays can be  
29 used in the raw state as originally mined or can be  
30 initially subjected to calcination, acid treatment or  
31 chemical modification.

32

33

34

-17-

01 In addition to the foregoing materials, the SSZ-31 zeolites  
02 can be composited with porous matrix materials and mixtures  
03 of matrix materials such as silica, alumina, titania,  
04 magnesia, silica:alumina, silica-magnesia, silica-zirconia,  
05 silica-thoria, silica-beryllia, silica-titania,  
06 titania-zirconia as well as ternary compositions such as  
07 silica-alumina-thoria, silica-alumina-zirconia,  
08 silica-alumina-magnesia, and silica-magnesia-zirconia. The  
09 matrix can be in the form of a cogel.

10  
11 The SSZ-31 zeolites can also be composited with other  
12 zeolites such as synthetic and natural faujasites (e.g., X  
13 and Y), erionites, and mordenites. They can also be  
14 composited with purely synthetic zeolites such as those of  
15 the ZSM series. The combination of zeolites can also be  
16 composited in a porous inorganic matrix.

17  
18 SSZ-31 zeolites are useful in hydrocarbon conversion  
19 reactions. Hydrocarbon conversion reactions are chemical  
20 and catalytic processes in which carbon-containing compounds  
21 are changed to different carbon-containing compounds.  
22 Examples of hydrocarbon conversion reactions include  
23 catalytic cracking, hydrocracking, and olefin and aromatics  
24 formation reactions. The catalysts are useful in other  
25 petroleum refining and hydrocarbon conversion reactions such  
26 as isomerizing n-paraffins and naphthenes, polymerizing and  
27 oligomerizing olefinic or acetylenic compounds such as  
28 isobutylene and butene-1, reforming, alkylating, isomerizing  
29 polyalkyl substituted aromatics (e.g., ortho xylene), and  
30 disproportionating aromatics (e.g., toluene) to provide  
31 mixtures of benzene, xylenes, and higher methylbenzenes.  
32 The SSZ-31 catalysts have high selectivity, and under  
33 hydrocarbon conversion conditions can provide a high  
34 percentage of desired products relative to total products.

-18-

01 SSZ-31 zeolites can be used in processing hydrocarbonaceous  
02 feedstocks. Hydrocarbonaceous feedstocks contain carbon  
03 compounds and can be from many different sources, such as  
04 virgin petroleum fractions, recycle petroleum fractions,  
05 shale oil, liquefied coal, tar sand oil, and in general, can  
06 be any carbon containing fluid susceptible to zeolitic  
07 catalytic reactions. Depending on the type of processing  
08 the hydrocarbonaceous feed is to undergo, the feed can  
09 contain metal or be free of metals, it can also have high or  
10 low nitrogen or sulfur impurities. It can be appreciated,  
11 however, that processing will generally be more efficient  
12 (and the catalyst more active) if the metal, nitrogen, and  
13 sulfur content of the feedstock is lower.

14  
15 Using the SSZ-31 catalyst which contains aluminum framework  
16 substitution and a hydrogenation promoter, heavy petroleum  
17 residual feedstocks, cyclic stocks, and other hydrocracking  
18 charge stocks can be hydrocracked at hydrocracking  
19 conditions including a temperature in the range of from  
20 175°C to 485°C, molar ratios of hydrogen to hydrocarbon  
21 charge from 1 to 100, a pressure in the range of from 0.5 to  
22 350 bar, and a liquid hourly space velocity (LHSV) in the  
23 range of from 0.1 to 30.

24  
25 Hydrocracking catalysts comprising SSZ-31 contain an  
26 effective amount of at least one hydrogenation catalyst  
27 (component) of the type commonly employed in hydrocracking  
28 catalysts. The hydrogenation component is generally  
29 selected from the group of hydrogenation catalysts  
30 consisting of one or more metals of Group VIB and Group  
31 VIII, including the salts, complexes, and solutions  
32 containing such. The hydrogenation catalyst is preferably  
33 selected from the group of metals, salts, and complexes  
34 thereof of the group consisting of at least one of platinum,

-19-

01 palladium, rhodium, iridium, and mixtures thereof or the  
02 group consisting of at least one of nickel, molybdenum,  
03 cobalt, tungsten, titanium, chromium, and mixtures thereof.  
04 Reference to the catalytically active metal or metals is  
05 intended to encompass such metal or metals in the elemental  
06 state or in some form such as an oxide, sulfide, halide,  
07 carboxylate, and the like.

08

09 A hydrogenation component is present in the hydrocracking  
10 catalyst in an effective amount to provide the hydrogenation  
11 function of the hydrocracking catalyst and preferably in the  
12 range of from 0.05% to 25% by weight.

13

14 SSZ-31 may be used to dewax a variety of feedstocks ranging  
15 from relatively light distillate fractions up to high  
16 boiling stocks such as whole crude petroleum, reduced  
17 crudes, vacuum tower residua, cycle oils, synthetic crudes  
18 (e.g., shale oils, tar sand oil, etc.), gas oils, vacuum gas  
19 oils, foots oils, and other heavy oils. The feedstock will  
20 normally be a C<sub>10</sub>+ feedstock generally boiling above about  
21 350°F since lighter oils will usually be free of significant  
22 quantities of waxy components. However, the process is  
23 particularly useful with waxy distillate stocks such as  
24 middle distillate stocks including gas oils, kerosenes, and  
25 jet fuels, lubricating oil stocks, heating oils and other  
26 distillate fractions whose pour point and viscosity need to  
27 be maintained within certain specification limits.

28

29 Lubricating oil stocks will generally boil above 230°C  
30 (450°F), more usually above 315°C (600°F). Hydrocracked  
31 stocks are a convenient source of lubricating stocks of this  
32 kind and also of other distillate fractions since they  
33 normally contain significant amounts of waxy n-paraffins.  
34 The feedstock of the present process will normally be a C<sub>10</sub>+

-20-

01 feedstock containing paraffins, olefins, naphthenes,  
02 aromatics and heterocyclic compounds and with a substantial  
03 proportion of higher molecular weight n-paraffins and  
04 slightly branched paraffins which contribute to the waxy  
05 nature of the feedstock.

06

07 The catalytic dewaxing conditions are dependent on large  
08 measure on the feed used and upon the desired pour point.  
09 Generally, the temperature will be between about 200°C and  
10 about 475°C, preferably between about 250°C and about 450°C.  
11 The pressure is typically between about 15 psig and about  
12 3000 psig, preferably between about 200 psig and 3000 psig.  
13 The liquid hourly space velocity (LHSV) preferably will be  
14 from 0.1 to 20, preferably between about 0.2 and about 10.

15

16 Hydrogen is preferably present in the reaction zone during  
17 the catalytic dewaxing process. The hydrogen to feed ratio  
18 is typically between about 500 and about 30,000 SCF/bbl  
19 (standard cubic feet per barrel), preferably about 1,000 to  
20 about 20,000 SCF/bbl. Generally, hydrogen will be separated  
21 from the product and recycled to the reaction zone.  
22 Typical feedstocks include light gas-oil, heavy gas-oils, and  
23 reduced crudes boiling about 350°F.

24

25 The SSZ-31 hydrodewaxing catalyst may optionally contain a  
26 hydrogenation component of the type commonly employed in  
27 dewaxing catalysts. The hydrogenation component may be  
28 selected from the group of hydrogenation catalysts consist-  
29 ing of one or more metals of Group VIB and Group VIII,  
30 including the salts, complexes and solutions containing such  
31 metals. The preferred hydrogenation catalyst is at least  
32 one of the group of metals, salts, and complexes selected  
33 from the group consisting of at least one of platinum,  
34 palladium, rhodium, iridium, and mixtures thereof or at

-21-

01 least one from the group consisting of nickel, molybdenum,  
02 cobalt, tungsten, titanium, chromium, and mixtures thereof.  
03 Reference to the catalytically active metal or metals is  
04 intended to encompass such metal or metals in the elemental  
05 state or in some form such as an oxide, sulfide, halide,  
06 carboxylate, and the like.

07

08 The hydrogenation component of the hydrodewaxing catalyst is  
09 present in an effective amount to provide an effective  
10 hydrodewaxing catalyst preferably in the range of from about  
11 0.05 to 5% by weight.

12

13 The SSZ-31 hydrodewaxing catalyst may be used alone or in  
14 conjunction with intermediate-pore (or medium-pore)  
15 molecular sieves. These intermediate-pore molecular sieves  
16 are shape selective in that they have a pore size which  
17 admits straight-chain n-paraffins either alone or with only  
18 slightly branched-chain paraffins but which exclude more  
19 highly branched materials and cycloaliphatics. Molecular  
20 sieves such as ZSM-5, ZSM-11, ZSM-12, ZSM-22, ZSM-23 and  
21 SAPO-11 are suitable for this purpose.

22

23 The intermediate-pore molecular sieves may be combined with  
24 the SSZ-31 or the isomerization dewaxing step using SSZ-31  
25 may be followed by a separate selective dewaxing step using  
26 the intermediate-pore molecular sieves.

27

28 The relative amounts of the SSZ-31 component and shape  
29 selective intermediate-pore molecular sieve component, if  
30 any, will depend at least in part, on the selected hydro-  
31 carbon feedstock and on the desired product distribution to  
32 be obtained therefrom, but in all instances an effective  
33 amount of SSZ-31 is employed. When a shape selective  
34 molecular sieve component is employed, the relative weight

-22-

01 ratio of the shape selective molecular sieve to the SSZ-31  
02 is generally between about 10:1 and about 1:500, desirably  
03 between about 10:1 and about 1:200, preferably between about  
04 2:1 and about 1:50, and most preferably is between about 1:1  
05 and about 1:20.

06  
07 SSZ-31 can be used to convert light straight run naphthas  
08 and similar mixtures to highly aromatic mixtures. Thus,  
09 normal and slightly branched chained hydrocarbons, prefer-  
10 ably having a boiling range above about 40°C and less than  
11 about 200°C, can be converted to products having a  
12 substantial aromatics content by contacting the hydrocarbon  
13 feed with the zeolite at a temperature in the range of from  
14 about 400°C to 600°C, preferably 480°C to 550°C at pressures  
15 ranging from atmospheric to 10 bar, and LHSV ranging from  
16 0.1 to 15.

17  
18 The conversion catalyst preferably contain a Group VIII  
19 metal compound to have sufficient activity for commercial  
20 use. By Group VIII metal compound as used herein is meant  
21 the metal itself or a compound thereof. The Group VIII  
22 noble metals and their compounds, platinum, palladium, and  
23 iridium, or combinations thereof can be used. The most  
24 preferred metal is platinum. The amount of Group VIII metal  
25 present in the conversion catalyst should be within the  
26 normal range of use in reforming catalysts, from about 0.05  
27 to 2.0 wt. %, preferably 0.2 to 0.8 wt. %.

28  
29 The zeolite/Group VIII metal conversion catalyst can be used  
30 without a binder or matrix. The preferred inorganic matrix,  
31 where one is used, is a silica-based binder such as  
32 Cab-O-Sil or Ludox. Other matrices such as magnesia and  
33 titania can be used. The preferred inorganic matrix is  
34 nonacidic.

-23-

01 It is critical to the selective production of aromatics in  
02 useful quantities that the conversion catalyst be  
03 substantially free of acidity, for example, by poisoning the  
04 zeolite with a basic metal, e.g., alkali metal, compound.  
05 The zeolite is usually prepared from mixtures containing  
06 alkali metal hydroxides and thus, have alkali metal contents  
07 of about 1-2 wt. %. These high levels of alkali metal,  
08 usually sodium or potassium, are unacceptable for most  
09 catalytic applications because they greatly deactivate the  
10 catalyst for cracking reactions. Usually, the alkali metal  
11 is removed to low levels by ion exchange with hydrogen or  
12 ammonium ions. By alkali metal compound as used herein is  
13 meant elemental or ionic alkali metals or their basic  
14 compounds. Surprisingly, unless the zeolite itself is  
15 substantially free of acidity, the basic compound is  
16 required in the present process to direct the synthetic  
17 reactions to aromatics production.

18  
19 The amount of alkali metal necessary to render the zeolite  
20 substantially free of acidity can be calculated using  
21 standard techniques based on the aluminum, gallium or iron  
22 content of the zeolite. If a zeolite free of alkali metal  
23 is the starting material, alkali metal ions can be ion  
24 exchanged into the zeolite to substantially eliminate the  
25 acidity of the zeolite. An alkali metal content of about  
26 100%, or greater, of the acid sites calculated on a molar  
27 basis is sufficient.

28  
29 Where the basic metal content is less than 100% of the acid  
30 sites on a molar basis, the test described in U.S. Patent  
31 No. 4,347,394 which patent is incorporated herein by  
32 reference, can be used to determine if the zeolite is  
33 substantially free of acidity.

34

-24-

01 The preferred alkali metals are sodium, potassium, and  
02 cesium. The zeolite itself can be substantially free of  
03 acidity only at very high silica:alumina mole ratios; by  
04 "zeolite consisting essentially of silica" is meant a  
05 zeolite which is substantially free of acidity without base  
06 poisoning.

07  
08 Hydrocarbon cracking stocks can be catalytically cracked in  
09 the absence of hydrogen using SSZ-31 at LHSV from 0.5 to 50,  
10 temperatures from about 260°F to 1625°F and pressures from  
11 subatmospheric to several hundred atmospheres, typically  
12 from about atmospheric to about five atmospheres.

13  
14 For this purpose, the SSZ-31 catalyst can be composited with  
15 mixtures of inorganic oxide supports as well as traditional  
16 cracking catalyst.

17  
18 The catalyst may be employed in conjunction with traditional  
19 cracking catalysts, e.g., any aluminosilicate heretofore  
20 employed as a component in cracking catalysts.

21 Representative of the zeolitic aluminosilicates disclosed  
22 heretofore as employable as component parts of cracking  
23 catalysts are Zeolite Y (including steam stabilized  
24 chemically modified, e.g., ultra-stable Y), Zeolite X,  
25 Zeolite beta (U.S. Patent No. 3,308,069), Zeolite ZK-20  
26 (U.S. Patent No. 3,445,727), Zeolite ZSM-3 (U.S. Patent No.  
27 3,415,736), faujasite, LZ-10 (U.K. Patent 2,014,970, June 9,  
28 1982), ZSM-5-Type Zeolites, e.g., ZSM-5, ZSM-11, ZSM-12,  
29 ZSM-23, ZSM-35, ZSM-38, ZSM-48, crystalline silicates such  
30 as silicalite (U.S. Patent No. 4,061,724), erionite,  
31 mordenite, offretite, chabazite, FU-1-type zeolite, NU-type  
32 zeolites, LZ-210-type zeolite and mixtures thereof.  
33 Traditional cracking catalysts containing amounts of Na<sub>2</sub>O  
34 less than about one percent by weight are generally

-25-

01 preferred. The relative amounts of the SSZ-31 component and  
02 traditional cracking component, if any, will depend at least  
03 in part, on the selected hydrocarbon feedstock and on the  
04 desired product distribution to be obtained therefrom, but  
05 in all instances, an effective amount of SSZ-31 is employed.  
06 When a traditional cracking catalyst (TC) component is  
07 employed, the relative weight ratio of the TC to the SSZ-31  
08 is generally between about 1:10 and about 500:1, desirably  
09 between about 1:10 and about 200:1, preferably between about  
10 1:2 and about 50:1, and most preferably between about 1:1  
11 and about 20:1.

12

13 The cracking catalysts are typically employed with an  
14 inorganic oxide matrix component which may be any of the  
15 inorganic oxide matrix components which have been employed  
16 heretofore in the formulation of FCC catalysts including:  
17 amorphous catalytic inorganic oxides, e.g., catalytically  
18 active silica-aluminas, clays, silicas, aluminas,  
19 silica-aluminas, silica-zirconias, silica-magnesias,  
20 alumina-borias, alumina-titanias, and the like and mixtures  
21 thereof. The traditional cracking component and SSZ-31 may  
22 be mixed separately with the matrix component and then mixed  
23 or the TC component and SSZ-31 may be mixed and then formed  
24 with the matrix component.

25

26 The mixture of a traditional cracking catalyst and SSZ-31  
27 may be carried out in any manner which results in the  
28 coincident presence of such in contact with the crude oil  
29 feedstock under catalytic cracking conditions. For example,  
30 a catalyst may be employed containing the traditional  
31 cracking catalyst and a SSZ-31 in single catalyst particles  
32 or SSZ-31 with or without a matrix component may be added as  
33 a discrete component to a traditional cracking catalyst.

34

-26-

01 SSZ-31 can also be used to oligomerize straight and branched  
02 chain olefins having from about 2-21 and preferably 2-5  
03 carbon atoms. The oligomers which are the products of the  
04 process are medium to heavy olefins which are useful for  
05 both fuels, i.e., gasoline or a gasoline blending stock and  
06 chemicals.

07

08 The oligomerization process comprises contacting the olefin  
09 feedstock in the gaseous state phase with SSZ-31 at a  
10 temperature of from about 450°F to about 1200°F, a WHSV of  
11 from about 0.2 to about 50 and a hydrocarbon partial  
12 pressure of from about 0.1 to about 50 atmospheres.

13

14 Also, temperatures below about 450°F may be used to  
15 oligomerize the feedstock, when the feedstock is in the  
16 liquid phase when contacting the zeolite catalyst. Thus,  
17 when the olefin feedstock contacts the zeolite catalyst in  
18 the liquid phase, temperatures of from about 50°F to about  
19 450°F, and preferably from 80 to 400°F may be used and a  
20 WHSV of from about 0.05 to 20 and preferably 0.1 to 10. It  
21 will be appreciated that the pressures employed must be  
22 sufficient to maintain the system in the liquid phase. As  
23 is known in the art, the pressure will be a function of the  
24 number of carbon atoms of the feed olefin and the  
25 temperature. Suitable pressures include from about 0 psig  
26 to about 3000 psig.

27

28 The zeolite can have the original cations associated  
29 therewith replaced by a wide variety of other cations  
30 according to techniques well known in the art. Typical  
31 cations would include hydrogen, ammonium, and metal cations  
32 including mixtures of the same. Of the replacing metallic  
33 cations, particular preference is given to cations of metals  
34 such as rare earth metals, manganese, calcium, as well as

-27-

01 metals of Group II of the Periodic Table, e.g., zinc, and  
02 Group VIII of the Periodic Table, e.g., nickel. One of the  
03 prime requisites is that the zeolite have a fairly low  
04 aromatization activity, i.e., in which the amount of  
05 aromatics produced is not more than about 20 wt. %. This is  
06 accomplished by using a zeolite with controlled acid  
07 activity [alpha value] of from about 0.1 to about 120,  
08 preferably from about 0.1 to about 100, as measured by its  
09 ability to crack n-hexane.

10

11 Alpha values are defined by a standard test known in the  
12 art, e.g., as shown in U.S. Patent No. 3,960,978 which is  
13 incorporated herein by reference. If required, such  
14 zeolites may be obtained by steaming, by use in a conversion  
15 process or by any other method which may occur to one  
16 skilled in this art.

17

18 SSZ-31 can be used to convert light gas  $C_2-C_6$  paraffins  
19 and/or olefins to higher molecular weight hydrocarbons  
20 including aromatic compounds. Operating temperatures of  
21 100-700°C, operating pressures of 0-1000 psig and space  
22 velocities of  $0.5-40 \text{ hr}^{-1}$  WHSV can be used to convert the  
23  $C_2-C_6$  paraffin and/or olefins to aromatic compounds.  
24 Preferably, the zeolite will contain a catalyst metal or  
25 metal oxide wherein said metal is selected from the group  
26 consisting of Group IB, IIB, IIIA, or VIII of the Periodic  
27 Table, and most preferably, gallium or zinc and in the range  
28 of from about 0.05-5 wt. %.

29

30 SSZ-31 can be used to condense lower aliphatic alcohols  
31 having 1-10 carbon atoms to a gasoline boiling point  
32 hydrocarbon product comprising mixed aliphatic and aromatic  
33 hydrocarbons. Preferred condensation reaction condition  
34 using SSZ-31 as the condensation catalyst include a

-28-

01 temperature of about 500-1000°F, a pressure of about  
02 0.5-1000 psig and a space velocity of about 0.5-50 WHSV.  
03 U.S. Patent No. 3,984,107 describes the condensation process  
04 conditions in more detail. The disclosure of U.S. Patent  
05 No. 3,984,107 is incorporated herein by reference.

06

07 The SSZ-31 catalyst may be in the hydrogen form or may be  
08 base exchanged or impregnated to contain ammonium or a metal  
09 cation complement, preferably in the range of from about  
10 0.05-5 wt. %. The metal cations that may be present include  
11 any of the metals of the Groups I-VIII of the Periodic  
12 Table. However, in the case of Group IA metals, the cation  
13 content should in no case be so large as to effectively  
14 inactivate the catalyst.

15

16 The present SSZ-31 catalyst is highly active and highly  
17 selective for isomerizing C<sub>4</sub> to C<sub>7</sub> hydrocarbons. The  
18 activity means that the catalyst can operate at relatively  
19 low temperatures which thermodynamically favors highly  
20 branched paraffins. Consequently, the catalyst can produce  
21 a high octane product. The high selectivity means that a  
22 relatively high liquid yield can be achieved when the  
23 catalyst is run at a high octane.

24

25 The isomerization process comprises contacting the  
26 isomerization catalyst with a hydrocarbon feed under  
27 isomerization conditions. The feed is preferably a light  
28 straight run fraction, boiling within the range of 30-250°F  
29 and preferably from 60-200°F. Preferably, the hydrocarbon  
30 feed for the process comprises a substantial amount of C<sub>4</sub> to  
31 C<sub>7</sub> normal and slightly branched low octane hydrocarbons,  
32 more preferably C<sub>5</sub> and C<sub>6</sub> hydrocarbons.

33

34

-29-

01 The pressure in the process is preferably between 50-1000  
02 psig, more preferably between 100-500 psig. The LHSV is  
03 preferably between about 1 to about 10 with a value in the  
04 range of about 1 to about 4 being more preferred. It is  
05 also preferable to carry out the isomerization reaction in  
06 the presence of hydrogen. Preferably, hydrogen is added to  
07 give a hydrogen to hydrocarbon ratio ( $H_2/HC$ ) of between 0.5  
08 and 10  $H_2/HC$ , more preferably between 1 and 8  $H_2/HC$ . The  
09 temperature is preferably between about 200°F and about  
10 1000°F, more preferably between 400-600°F. As is well known  
11 to those skilled in the isomerization art, the initial  
12 selection of the temperature within this broad range is made  
13 primarily as a function of the desired conversion level  
14 considering the characteristics of the feed and of the  
15 catalyst. Thereafter, to provide a relatively constant  
16 value for conversion, the temperature may have to be slowly  
17 increased during the run to compensate for any deactivation  
18 that occurs.

19  
20 A low sulfur feed is especially preferred in the  
21 isomerization process. The feed preferably contains less  
22 than 10 ppm, more preferably less than 1 ppm, and most  
23 preferably less than 0.1 ppm sulfur. In the case of a feed  
24 which is not already low in sulfur, acceptable levels can be  
25 reached by hydrogenating the feed in a presaturation zone  
26 with a hydrogenating catalyst which is resistant to sulfur  
27 poisoning. An example of a suitable catalyst for this  
28 hydrodesulfurization process is an alumina-containing  
29 support and a minor catalytic proportion of molybdenum  
30 oxide, cobalt oxide and/or nickel oxide. A platinum on  
31 alumina hydrogenating catalyst can also work. In which  
32 case, a sulfur sorber is preferably placed downstream of the  
33 hydrogenating catalyst, but upstream of the present  
34 isomerization catalyst. Examples of sulfur sorbers are

-30-

01 alkali or alkaline earth metals on porous refractory  
02 inorganic oxides, zinc, etc. Hydrodesulfurization is  
03 typically conducted at 315-455°C, at 200-2000 psig, and at a  
04 LHSV of 1-5.

05

06 It is preferable to limit the nitrogen level and the water  
07 content of the feed. Catalysts and processes which are  
08 suitable for these purposes are known to those skilled in  
09 the art.

10

11 After a period of operation, the catalyst can become  
12 deactivated by sulfur or coke. Sulfur and coke can be  
13 removed by contacting the catalyst with an oxygen-containing  
14 gas at an elevated temperature. If the Group VIII metal(s)  
15 has agglomerated, then it can be redispersed by contacting  
16 the catalyst with a chlorine gas under conditions effective  
17 to redisperse the metal(s). The method of regenerating the  
18 catalyst may depend on whether there is a fixed bed, moving  
19 bed, or fluidized bed operation. Regeneration methods and  
20 conditions are well known in the art.

21

22 The conversion catalyst preferably contains a Group VIII  
23 metal compound to have sufficient activity for commercial  
24 use. By Group VIII metal compound as used herein is meant  
25 the metal itself or a compound thereof. The Group VIII  
26 noble metals and their compounds, platinum, palladium, and  
27 iridium, or combinations thereof can be used. Rhenium and  
28 tin may also be used in conjunction with the noble metal.  
29 The most preferred metal is platinum. The amount of Group  
30 VIII metal present in the conversion catalyst should be  
31 within the normal range of use in isomerizing catalysts,  
32 from about 0.05-2.0 wt. %.

33

34

-31-

01 SSZ-31 can be used in a process for the alkylation or  
02 transalkylation of an aromatic hydrocarbon. The process  
03 comprises contacting the aromatic hydrocarbon with a  $C_2$  to  
04  $C_4$  olefin alkylating agent or a polyalkyl aromatic  
05 hydrocarbon transalkylating agent, under at least partial  
06 liquid phase conditions, and in the presence of a catalyst  
07 comprising SSZ-31.

08

09 For high catalytic activity, the SSZ-31 zeolite should be  
10 predominantly in its hydrogen ion form. Generally, the  
11 zeolite is converted to its hydrogen form by ammonium  
12 exchange followed by calcination. If the zeolite is  
13 synthesized with a high enough ratio of organonitrogen  
14 cation to sodium ion, calcination alone may be sufficient.  
15 It is preferred that, after calcination, at least 80% of the  
16 cation sites are occupied by hydrogen ions and/or rare earth  
17 ions.

18

19 The pure SSZ-31 zeolite may be used as a catalyst, but  
20 generally, it is preferred to mix the zeolite powder with an  
21 inorganic oxide binder such as alumina, silica,  
22 silica-alumina, or naturally occurring clays and form the  
23 mixture into tablets or extrudates. The final catalyst may  
24 contain from 1-99 wt. % SSZ-31 zeolite. Usually the zeolite  
25 content will range from 10-90 wt. %, and more typically from  
26 60-80 wt. %. The preferred inorganic binder is alumina.  
27 The mixture may be formed into tablets or extrudates having  
28 the desired shape by methods well known in the art.

29

30 Examples of suitable aromatic hydrocarbon feedstocks which  
31 may be alkylated or transalkylated by the process of the  
32 invention include aromatic compounds such as benzene,  
33  
34

-32-

01 toluene, and xylene. The preferred aromatic hydrocarbon is  
02 benzene. Mixtures of aromatic hydrocarbons may also be  
03 employed.

04

05 Suitable olefins for the alkylation of the aromatic  
06 hydrocarbon are those containing 2-20 carbon atoms, such as  
07 ethylene, propylene, butene-1, transbutene-2, and  
08 cis-butene-2, or mixtures thereof. The preferred olefin is  
09 propylene. These olefins may be present in admixture with  
10 the corresponding C<sub>2</sub> to C<sub>4</sub> paraffins, but it is preferable  
11 to remove any dienes, acetylenes, sulfur compounds or  
12 nitrogen compounds which may be present in the olefin  
13 feedstock stream to prevent rapid catalyst deactivation.

14

15 When transalkylation is desired, the transalkylating agent  
16 is a polyalkyl aromatic hydrocarbon containing two or more  
17 alkyl groups that each may have from two to about four  
18 carbon atoms. For example, suitable polyalkyl aromatic  
19 hydrocarbons include di-, tri-, and tetra-alkyl aromatic  
20 hydrocarbons, such as diethylbenzene, triethylbenzene,  
21 diethylmethylbenzene (diethyltoluene), di-isopropylbenzene,  
22 di-isopropyltoluene, dibutylbenzene, and the like.  
23 Preferred polyalkyl aromatic hydrocarbons are the dialkyl  
24 benzenes. A particularly preferred polyalkyl aromatic  
25 hydrocarbon is di-isopropylbenzene.

26

27 Reaction products which may be obtained include ethylbenzene  
28 from the reaction of benzene with either ethylene or  
29 polyethylbenzenes, cumene from the reaction of benzene with  
30 propylene or polyisopropylbenzenes, ethyltoluene from the  
31 reaction of toluene with ethylene or polyethyltoluenes,  
32 cymenes from the reaction of toluene with propylene or  
33 polyisopropyltoluenes, and secbutylbenzene from the reaction  
34 of benzene and n-butenes or polybutylbenzenes. The

-33-

01 production of cumene from the alkylation of benzene with  
02 propylene or the transalkylation of benzene with  
03 di-isopropylbenzene is especially preferred.

04

05 When alkylation is the process conducted, reaction  
06 conditions are as follows. The aromatic hydrocarbon feed  
07 should be present in stoichiometric excess. It is preferred  
08 that molar ratio of aromatics to olefins be greater than  
09 four-to-one to prevent rapid catalyst fouling. The reaction  
10 temperature may range from 100-600°F, preferably, 250-450°F.  
11 The reaction pressure should be sufficient to maintain at  
12 least a partial liquid phase in order to retard catalyst  
13 fouling. This is typically 50-1000 psig depending on the  
14 feedstock and reaction temperature. Contact time may range  
15 from 10 seconds to 10 hours, but is usually from five  
16 minutes to an hour. The WHSV, in terms of grams (pounds) of  
17 aromatic hydrocarbon and olefin per gram (pound) of catalyst  
18 per hour, is generally within the range of about 0.5 to 50.

19

20 When transalkylation is the process conducted, the molar  
21 ratio of aromatic hydrocarbon will generally range from  
22 about 1:1 to 25:1, and preferably from about 2:1 to 20:1.  
23 The reaction temperature may range from about 100-600°F, but  
24 it is preferably about 250-450°F. The reaction pressure  
25 should be sufficient to maintain at least a partial liquid  
26 phase, typically in the range of about 50-1000 psig,  
27 preferably 300-600 psig. The WHSV will range from about  
28 0.1-10.

29

30 The conversion of hydrocarbonaceous feeds can take place in  
31 any convenient mode, for example, in fluidized bed, moving  
32 bed, or fixed bed reactors depending on the types of process

33

34

-34-

01 desired. The formulation of the catalyst particles will  
02 vary depending on the conversion process and method of  
03 operation.

04  
05 Other reactions which can be performed using the catalyst of  
06 this invention containing a metal, e.g., platinum, include  
07 hydrogenation-dehydrogenation reactions, denitrogenation,  
08 and desulfurization reactions.

09  
10 Some hydrocarbon conversions can be carried out on SSZ-31  
11 zeolites utilizing the large pore shape-selective behavior.  
12 For example, the substituted SSZ-31 zeolite may be used in  
13 preparing cumene or other alkylbenzenes in processes  
14 utilizing propylene to alkylate aromatics. Such a process  
15 is described in our U.S. Serial No. 134,410 (1987), using  
16 beta zeolite.

17  
18 SSZ-31 can be used in hydrocarbon conversion reactions with  
19 active or inactive supports, with organic or inorganic  
20 binders, and with and without added metals. These reactions  
21 are well known to the art, as are the reaction conditions.

22  
23 SSZ-31 can also be used as an adsorbent, as a filler in  
24 paper and paint, and as a water-softening agent in  
25 detergents.

26  
27 The following examples illustrate the preparation of SSZ-31.

-35-

EXAMPLESExample 1

Preparation of N,N,N-Trimethyl-8-Ammonium  
Tricyclo[5.2.1.0] decane Hydroxide (Template A)

Five (5) grams of 8-ketotricyclo [5.2.1.0] decane (Aldrich Chemical Co.) was mixed with 2.63 gms of formic acid (88%) and 4.5 gms of dimethylformamide. The mixture was then heated in a pressure vessel for 16 hours at 190°C. Care should be taken to anticipate the increase in pressure the reaction experiences due to CO<sub>2</sub> evolution. The reaction was conveniently carried out in a Parr 4748 reactor with teflon liner. The workup consists of extracting N,N-dimethyl-8-amino tricyclo[5.2.1.0] decane from a basic (pH=12) aqueous solution with diethyl ether. The various extracts were dried with Na<sub>2</sub>SO<sub>4</sub>, the solvent removed and the product taken up in ethyl acetate. An excess of methyl iodide was added to a cooled solution which was then stirred at room temperature for several days. The crystals were collected and washed with diethyl ether to give N,N,N-trimethyl-8-ammonium tricyclo[5.2.1.0] decane iodide. The product has a melting point of 270-272°C and the elemental analyses and proton NMR are consistent with the expected structure. The vacuum-dried iodide salt was then ion-exchanged with ion-exchange resin AG 1x8 (in molar excess) to the hydroxide form. The exchange was performed over a column or more preferably by overnight stirring of the resin beads and the iodide salt in an aqueous solution designed to give about a 0.5 molar solution of the organic hydroxide. This is Template A (see Table 4).

-36-

Example 2

01  
02  
03 1.5 Millimoles of the template from Example 1 were mixed  
04 with 0.035 gm of NaOH (solid) in 7.5 ml H<sub>2</sub>O. 0.60 Gram of  
05 Cabosil M5 was stirred into the solution. The mixture was  
06 heated in a Parr 4745 reactor at 150°C and without agitation  
07 for 20 days. The contents of the reactor were filtered,  
08 washed with distilled water, dried at 100°C and analyzed by  
09 X-ray diffraction. The product was found to be the novel  
10 structure SSZ-31. The pattern is tabulated in Table 3  
11 below.

11	32.16	2.783	5
12	32.76	2.734	6

Example 3

The same reaction mixture of Example 2 was formed again. A Parr 4745 reactor was used but this time it was loaded onto a rotating (30 rpm) spit of a Blue M oven which was rotated at 30 RPM. The tumbling reactors were heated at 160°C for 6 days. The analogous work-up and analysis produced a crystalline SSZ-31.

Example 4

2.25 Millimoles of template were mixed with 0.075 gm of NaOH (solid) and 12 ml of H<sub>2</sub>O. 0.90 Gram of Cabosil were added and the reaction was run as in Example 3 except the Na/SiO<sub>2</sub> ratio had been increased. After 11 days of reaction, the product was mostly SSZ-31 but there was also some Kenyaitite and tridymite impurity.

Example 5

The same experiment as in Example 4 was repeated with the following few changes. NaOH was replaced by 0.09 gms of KOH (solid) and the reaction was run at 150°C and 0 RPM (no

-38-

01 stirring) and required 22 days to crystallize. The product  
02 was SSZ-31 with a small amount of amorphous material.

03

04

Example 6

05

06 Example 5 was repeated. However, the reaction was seeded  
07 with the product of Example 4. After 10 days at 160°C but  
08 without stirring the product was SSZ-31 with a small  
09 impurity of Kenyaitite. This run demonstrates that crys-  
10 tallization, in the absence of stirring, can be made faster  
11 by the use of seed crystals.

12

13

Example 7

14

15 (a) 5 Millimoles of the template of Example 1 and 0.06 gm  
16 NaOH(s) were mixed in 11.8 mL H<sub>2</sub>O. 0.90 Gram Cabosil was  
17 stirred in to produce a homogeneous solution. 0.19 Gram of  
18 Nalco 1SJ 612 (26% SiO<sub>2</sub>, 4% Al<sub>2</sub>O<sub>3</sub>) was added with stirring  
19 and several milligrams of seed crystals were also added.  
20 The sealed reaction was carried out at 160°C, 39 rpm, and  
21 over 10 days. The crystalline product was determined to be  
22 a very broadlined version of SSZ-31.

23

24 (b) When the same reaction was run without seed crystals  
25 and at 30 rpm, crystallization of SSZ-31 required 16 days.

26

27

Example 8

28

29 The same experiment as Example 7 was repeated, except the  
30 source of aluminum was 0.05 gms Y zeolite (SK-40). Seeds of  
31 SSZ-31 were once again added. After 10 days at 160°C and 30  
32 rpm, the product had a broadlined version of SSZ-31 although  
33 not as broadened as in Example 7.

34

-39-

Example 9

01

02

03 The crystalline products of Examples 2 and 4 were subjected  
04 to calcination as follows. The samples were heated in a  
05 muffle furnace from room temperature up to 540°C at a  
06 steadily increasing rate over a 7-hour period. The samples  
07 were maintained at 540°C for four more hours and then taken  
08 up to 600°C for an additional four hours. A 50/50 mixture  
09 of air and nitrogen was passed over the zeolite at a rate of  
10 20 standard cubic feet per minute during heating. The cal-  
11 cined product of Example 2 had the X-ray diffraction lines  
12 indicated in Table 4 below.

Example 10

Ion-exchange of the calcined materials from Example 9 was carried out using  $\text{NH}_4\text{NO}_3$  to convert the zeolites from Na form to  $\text{NH}_4$  and then eventually to the H form. Typically, the same mass of  $\text{NH}_4\text{NO}_3$  as zeolite was slurried into  $\text{H}_2\text{O}$  at ratio of 50/1  $\text{H}_2\text{O}$  to zeolite. The exchange solution was heated at  $100^\circ\text{C}$  for two hours and then filtered. This process was repeated four times. Finally, after the last exchange, the zeolite was washed several times with  $\text{H}_2\text{O}$  and dried. A repeat calcination as in Example 9 was carried out but without the final treatment at  $600^\circ\text{C}$ . This produces the H form of the zeolites. The surface area for this material was  $300 \text{ m}^2/\text{gm}$ . The micro pore volume was  $0.12 \text{ cc/gm}$  as determined by the BET method with  $\text{N}_2$  as absorbate.

Example 11

The product of Example 7(b) was treated as in Examples 9 and 10. Next, the zeolite powder was pelletized in a Carver press at 1000 psi. The pellets were broken up and meshed to

-41-

01 24-40 size. 0.35 Gram of the hydrogen form was loaded into  
02 a 3/8-in. stainless steel tube with alumina packed on either  
03 side of the bed. The bed was heated in a Lindberg furnace  
04 and Helium (10 cc/min) was introduced into the reactor. The  
05 catalyst was heated to 700°F. Once temperature equilibra-  
06 tion was achieved, a 50/50 w/w feed of n-hexane/3 methyl-  
07 pentane was introduced into the reactor at WHSV = 0.68. The  
08 products were sampled on line by capillary G.C. At  
09 10 minutes onstream, the conversion was 36% and indicated a  
10 large pore zeolite.

#### 11 Example 12

12  
13  
14 45 grams of 4-dimethylamino-2,2,6,6-tetramethyl piperidine  
15 (Aldrich) is dissolved in 1.5 L of ethyl acetate. The  
16 solution is chilled in an ice bath and 80 g of methyl iodide  
17 is added dropwise with stirring. The reaction is allowed to  
18 come to room temperature and is stirred for a few days. The  
19 reaction is filtered. The solids are washed with  
20 tetrahydrofuran and ether and then vacuum dried.

21  
22 The crystalline salt is conveniently converted to the  
23 hydroxide form by stirring overnight in water with AG1-X8  
24 hydroxide ion exchange resin to achieve a solution ranging  
25 from 0.25-1.5 molar. This is Template B (see Table 2).

#### 26 Example 13

27  
28  
29 4 grams of 3 Azabicyclo [3.2.2] nonane is stirred into 100  
30 ml of methanol. 3 grams of potassium bicarbonate are added  
31 and the solution is chilled in an ice bath. Methyl iodide  
32 (10 gms) is added dropwise and the solution is stirred for  
33 15-25 hours. The inorganic solids are filtered off and the  
34 methanol solution is stripped down. The residue is treated

-42-

01 with  $\text{CHCl}_3$  which extracts the product. The clear  $\text{CHCl}_3$   
02 phase is now stripped down and the solid product is  
03 recrystallized from a minimum of hot methanol. Subsequent  
04 filtration, washing and ion-exchange is similar to Example  
05 12. This is Template C (see Table 2).

06

07 Example 14

08

09 Template D (see Table 2) is prepared beginning with  
10 bicyclo[3.2.1] octa-2-one. The reaction sequence and molar  
11 ratios are the same as in Example 1.

12

13 Example 15

14

15 Template E (see Table 2) is prepared from 6-Aza, 1,3,3  
16 Trimethyl-bicyclo[3.2.1] octane. The procedure and molar  
17 ratios parallel Example 13.

18

19 Example 16

20

21 3,5,5, Trimethyl azacycloheptane is alkylated with methyl  
22 iodide by the same procedure in Examples 13 and 15. The  
23 crystalline product is Template F (see Table 2).

24

25 Example 17

26

27 2.25 millimoles of the hydroxide form of the template from  
28 Example 12 and 0.09 g NaOH (solid) in a total of 12 mL  $\text{H}_2\text{O}$   
29 are stirred until clear. 0.90 g of  $\text{NH}_4^+$  boron beta  
30 (aluminum free and described in U.S. Serial No. 377,359) is  
31 added and the reaction is heated at  $160^\circ\text{C}$  for six days and  
32 at 30 rpm. The product after filtration and washing, drying  
33 at  $100^\circ\text{C}$ , and XRD analysis is found to be SSZ-31 and some  
34 quartz impurity. No remaining beta zeolite is observed.

-43-

Example 18

The same experiment as Example 17 is set up except the NaOH is reduced to 0.06 g. Seeds of all silica SSZ-31 are added (20 mg). Heating is carried out at 150°C for six days, without stirring. The product is pure SSZ-31.

Examples 19-23

The following examples in Table 5 demonstrate the synthesis of SSZ-31 containing boron using templates B, C, D, E and F.

TABLE 5

Synthesis of Boron SSZ-31 Zeolite  
(150°C, 4 days, 0 rpm)

Ex #	Template	mMoles as OH	1 N NaOH	H <sub>2</sub> O*	NH <sub>4</sub> Boron Beta	XRD
19	B	2.25	1.5	10.5	0.90 gms	SSZ-31
20	C	2.25	1.5	10.5	0.90 gms	SSZ-31
21	D	2.25	1.5	10.5	0.90 gms	SSZ-31
22	E	2.25	1.5	10.5	0.90 gms	SSZ-31
23	F	2.25	1.5	10.5	0.90 gms	SSZ-31

\*Includes contribution from template solution and additional water added.

Example 24

The X-ray diffraction data for the uncalcined product from Example 22 is presented in Table 6. The uncalcined product of Example 22 was calcined as follows. The sample was

-44-

01 heated in a muffle furnace from room temperature up to 540°C  
02 at a steadily increasing rate over a 7-hour period. The  
03 sample was maintained at 540°C for four more hours and then  
04 taken up to 600°C for an additional four hours. Nitrogen  
05 was passed over the zeolite at a rate of 20 standard cfm  
06 during heating. The calcined product had the X-ray  
07 diffraction lines indicated in Table 7 below.

Example 25

Ion exchange of the calcined material from Example 17 was carried out using  $\text{NH}_4\text{NO}_3$  to convert the zeolites from Na form to  $\text{NH}_4$ . Typically the same mass of  $\text{NH}_4\text{NO}_3$  as zeolite was slurried into  $\text{H}_2\text{O}$  at ratio of 50:1  $\text{H}_2\text{O}$ :zeolite. The exchange solution was heated at  $100^\circ\text{C}$  for two hours and then filtered. This process was repeated two times. Finally,

-46-

01 after the last exchange, the zeolite was washed several  
02 times with H<sub>2</sub>O and dried.

04

Example 26

05

06

Constraint Index Determination

07

08 0.50 g of the hydrogen form of the zeolite of Example 17  
09 (after treatment according to Examples 24 and 25) was packed  
10 into a 3/8-inch stainless steel tube with alundum on both  
11 sides of the zeolite bed. A lindburg furnace was used to  
12 heat the reactor tube. Helium was introduced into the  
13 reactor tube at 10 cc/minute and atmospheric pressure. The  
14 reactor was taken to 250°F for 40 minutes and then raised to  
15 800°F. Once temperature equilibration was achieved, a  
16 50/50, w/w feed of n-hexane and 3-methylpentane was  
17 introduced into the reactor at a rate of 0.62 cc/hour. Feed  
18 delivery was made via syringe pump. Direct sampling onto a  
19 gas chromatograph was begun after 10 minutes of feed  
20 introduction. Constraint Index values were calculated from  
21 gas chromatographic data using methods known in the art.

22

Example 29

The product of Example 7(a) was treated as in Examples 9 and 10. This catalyst now contained acidity due to aluminum incorporation. Two back ion-exchanges with KNO<sub>3</sub> were performed and the catalyst was calcined to 1000°F. Next, a reforming catalyst was prepared as in Example 28. The catalyst was evaluated under the following conditions:

psig = 200

H<sub>2</sub>/HC = 6.4

WHSV = 6

Temp. = 800°F

The feed has an iC<sub>7</sub> mixture (Philips Petroleum Company). The data for the run is given in Table 9. After 23 hours on stream, the temperature was raised to 900°F and this data also appears in the Table. By comparison with Example 28, the incorporation of aluminum into the zeolite gives a more active reforming catalyst.

05

Example 31

06

07 The acid form of SSZ-31 was prepared as in Example 27 and  
08 tested for the conversion of methanol to liquid products.  
09 0.5 gm of catalyst was loaded into a 3/8-inch stainless  
10 steel reactor tube which was heated in a Lindberg furnace to  
11 1000°F. The temperature was reduced to 700°F in a stream of  
12 helium at 20 cc/min. Methanol was introduced into the  
13 reactor at a rate of 1.15 cc/hr. The conversion at 5  
14 minutes was 100% and dropped over several hours. The  
15 product distribution is given in Table 11 below.

## 01 WHAT IS CLAIMED IS:

02

03 1. A zeolite having a mole ratio of an oxide selected from  
04 silicon oxide, germanium oxide and mixtures thereof to  
05 an oxide selected from aluminum oxide, gallium oxide,  
06 iron oxide, and mixtures thereof greater than about  
07 50:1, and having the X-ray diffraction lines of  
08 Table 1.

09

10 2. A zeolite having a mole ratio of an oxide selected from  
11 silicon oxide, germanium oxide, and mixtures thereof to  
12 an oxide selected from boron oxide or mixtures of boron  
13 oxide with aluminum oxide, gallium oxide, and iron  
14 oxide, greater than 50:1, and having the X-ray  
15 diffraction lines of Table 1.

16

17 3. A zeolite having a mole ratio of an oxide selected from  
18 silicon oxide, germanium oxide, and mixtures thereof to  
19 an oxide selected from boron oxide or mixtures of boron  
20 oxide with aluminum oxide, greater than 50:1, and  
21 having the X-ray diffraction lines of Table 1.

22

23 4. A zeolite having a mole ratio of silicon oxide to boron  
24 oxide greater than 50:1 and having the X-ray  
25 diffraction lines of Table 1.

26

27 5. A zeolite having a mole ratio of silicon oxide to  
28 aluminum oxide greater than about 50:1 and having the  
29 X-ray diffraction lines of Table 1.

30

31 6. A zeolite having a composition, as synthesized and in  
32 the anhydrous state in terms of mole ratios of oxides  
33 as follows:

34

-54-

01 (0.1 to 10)Q<sub>2</sub>O:(0.1 to 5.0)M<sub>2</sub>O:W<sub>2</sub>O<sub>3</sub>(greater than 50)YO<sub>2</sub>

wherein M is an alkali metal cation, W is selected from boron, Y is selected from silicon, germanium, and mixtures thereof, Q is a quaternary ammonium ion and having the X-ray diffraction lines of Table 1.

7. A zeolite prepared by thermally treating the zeolite of Claim 6 at a temperature from about 200°C to 820°C.

8. A zeolite in accordance with Claim 6 wherein the quaternary ammonium ion is derived from a compound of the formula:

9. A zeolite in accordance with Claim 6 wherein the quaternary ammonium ion is derived from a compound of the formula:

-55-

- 01 10. A zeolite in accordance with Claim 6 wherein the  
02 quaternary ammonium ion is derived from a compound of  
03 the formula:

- 11 11. A zeolite in accordance with Claim 6 wherein the  
12 quaternary ammonium ion is derived from a compound of  
13 the formula:

- 22 12. A zeolite in accordance with Claim 6 wherein the  
23 quaternary ammonium ion is derived from a compound of  
24 the formula:

-56-

- 01 13. A zeolite in accordance with Claim 1, 2 or 3 which has  
02 undergone ion exchange with hydrogen, ammonium, rare  
03 earth metal, Group IIA metal, or Group VIII metal ions.  
04
- 05 14. A zeolite in accordance with Claim 1, 2 or 3 wherein  
06 rare earth metals, Group IIA metals, or Group VIII  
07 metals are occluded in the zeolite.  
08
- 09 15. A zeolite composition, comprising the zeolite of  
10 Claim 1, 2 or 3 and an inorganic matrix.  
11
- 12 16. A method for preparing the zeolite of Claim 2,  
13 comprising:  
14
- 15 (a) preparing an aqueous mixture containing sources of  
16 a quaternary ammonium ion, an oxide selected from  
17 boron oxide in a borosilicate form, and an oxide  
18 selected from silicon oxide, germanium oxide, and  
19 mixtures thereof;  
20
- 21 (b) maintaining the mixture at a temperature of at  
22 least 140°C until the crystals of said zeolite  
23 form; and  
24
- 25 (c) recovering said crystals.  
26
- 27 17. A method in accordance with Claim 16 wherein the  
28 borosilicate is borosilicate glass, or boron beta  
29 zeolite.  
30
- 31 18. The method in accordance with Claim 16 wherein the  
32 aqueous mixture has a composition in terms of mole  
33 ratios of oxides falling in the ranges:  $YO_2/W_2O_3$ ,  
34 greater than 50;  $Q/YO_2$ , 0.05:1 to 0.50:1; wherein Y is

-57-

01 selected from silicon, germanium, and mixtures thereof,  
02 W is selected from boron and Q is a quaternary ammonium  
03 compound.  
04

- 05 19. A method in accordance with Claims 16 and 17 wherein  
06 the quaternary ammonium ion is derived from a compound  
07 of the formula:  
08

- 18 20. A method in accordance with Claims 16 and 17 wherein  
19 the quaternary ammonium ion is derived from a compound  
20 of the formula:  
21

- 28 21. A method in accordance with Claims 16 and 17 wherein  
29 the quaternary ammonium ion is derived from a compound  
30 of the formula:  
31

-58-

- 

- CN1CCCC(C)(C)C1

- 24 24. A method for replacing the boron in the zeolite of  
25 Claim 7 comprising contacting this boron-containing  
26 zeolite with an aqueous solution of a Group IIIA metal  
27 or a transition metal.

-59-

01 25. A compound having the formula:

02

03

04

26. A compound having the formula:

27. A compound having the formula:

28. A process for converting hydrocarbons comprising contacting a hydrocarbonaceous feed at hydrocarbon converting conditions with the zeolite of Claim 1.

-60-

- 01 29. A process in accordance with Claim 28 which is a  
02 hydrocracking process comprising contacting the  
03 hydrocarbon feedstock under hydrocracking conditions  
04 with the zeolite of Claim 1.  
05
- 06 30. A process in accordance with Claim 28 which is a  
07 process for preparing a high octane product having an  
08 increased aromatics content comprising:  
09
- 10 (a) contacting a hydrocarbonaceous feed, which com-  
11 prises normal and slightly branched hydrocarbons  
12 having a boiling range above about 40°C and less  
13 than about 200°C under aromatic conversion con-  
14 ditions with the zeolite of Claim 1, wherein said  
15 zeolite is substantially free of acidity; and  
16
- 17 (b) recovering a higher octane effluent.  
18
- 19 31. A process in accordance with Claim 30 wherein the  
20 zeolite contains a Group VIII metal component.  
21
- 22 32. A process in accordance with Claim 28 which is a  
23 hydrodewaxing process comprising contacting the  
24 hydrocarbon feedstock under hydrodewaxing conditions  
25 with the zeolite of Claim 1.  
26
- 27 33. A process in accordance with Claim 28 which is a  
28 catalytic cracking process comprising the step of  
29 contacting the hydrocarbon feedstock in a reaction zone  
30 under catalytic cracking conditions in the absence of  
31 added hydrogen with a catalyst comprising the zeolite  
32 of Claim 1.  
33  
34

-61-

- 01 34. A process in accordance with Claim 33 which is a  
02 catalytic cracking process comprising the step of  
03 contacting the hydrocarbon feedstock in a reaction zone  
04 under catalytic cracking conditions in the absence of  
05 added hydrogen with a catalyst composition comprising a  
06 component which is the zeolite of Claim 1 and a large  
07 pore size crystalline aluminosilicate cracking  
08 component.  
09
- 10 35. A process in accordance with Claim 34 with a catalyst  
11 composition comprising a component which is the zeolite  
12 of Claim 1 and a large pore size crystalline  
13 aluminosilicate cracking component.  
14
- 15 36. A process as defined in Claim 35 wherein the  
16 crystalline aluminosilicate cracking component has a  
17 pore size greater than 7.0 angstroms.  
18
- 19 37. A process in accordance with Claim 34 wherein the  
20 catalyst compositions comprise a physical mixture of  
21 the two components.  
22
- 23 38. A process in accordance with Claim 34 wherein one of  
24 the components is the zeolite of Claim 1 incorporated  
25 in an inorganic oxide such as silica, alumina,  
26 amorphous silica-alumina, silica-magnesia, silica  
27 zirconia, alumina-boria, alumina-titanate, a synthetic  
28 clay such as synthetic mica-montmorillonite, natural  
29 clays such as kaolin, halloysite, montmorillonite,  
30 attapulgite, sepiolite, and saponite, acid activated  
31 clays, pillared or cross-linked clays, and mixtures  
32 thereof.  
33  
34

-62-

- 01 39. A process in accordance with Claim 34 wherein the two  
02 catalyst components are incorporated in an inorganic  
03 matrix comprised of the inorganic oxide of Claim 35.  
04
- 05 40. A process in accordance with Claim 28 which is an  
06 isomerizing process for isomerizing C<sub>4</sub> to C<sub>7</sub>  
07 hydrocarbons, comprising contacting a catalyst,  
08 comprising at least one Group VIII metal and the  
09 zeolite of Claim 1, with a feed having normal and  
10 slightly branched C<sub>4</sub> to C<sub>7</sub> hydrocarbons under  
11 isomerization conditions.  
12
- 13 41. A process in accordance with Claim 40 wherein the  
14 catalyst has been calcined in a steam/air mixture at an  
15 elevated temperature after impregnation of the Group  
16 VIII metal.  
17
- 18 42. A process in accordance with Claim 40 wherein Group  
19 VIII metal is platinum.  
20
- 21 43. A process in accordance with Claim 28 which is a  
22 process for alkylating an aromatic hydrocarbon which  
23 comprises contacting under alkylating conditions at  
24 least a mole excess of an aromatic hydrocarbon with a  
25 C<sub>2</sub> to C<sub>20</sub> olefin under at least partial liquid phase  
26 conditions and in the presence of a zeolite according  
27 to Claim 1.  
28
- 29 44. A process in accordance with Claim 43 wherein the  
30 aromatic hydrocarbon and olefin are present in a molar  
31 ratio of about 4:1 to 20:1, respectively.  
32  
33  
34

-63-

- 01 45. A process in accordance with Claim 43 wherein the  
02 aromatic hydrocarbon is a member selected from the  
03 group consisting of benzene, toluene and xylene, or  
04 mixtures thereof.  
05
- 06 46. A process in accordance with Claim 28 which is a  
07 process for transalkylating an aromatic hydrocarbon  
08 which comprises contacting under transalkylating  
09 conditions an aromatic hydrocarbon with a polyalkyl  
10 aromatic hydrocarbon under at least partial liquid  
11 phase conditions and in the presence of a zeolite  
12 according to Claim 1.  
13
- 14 47. A process in accordance with Claim 46 wherein said  
15 aromatic hydrocarbon and said polyalkyl aromatic  
16 hydrocarbon are present in a molar ratio of about 1:1  
17 to about 25:1, respectively.  
18
- 19 48. A process in accordance with Claim 46 wherein the  
20 aromatic hydrocarbon is a member selected from the  
21 group consisting of benzene, toluene and xylene, or  
22 mixtures thereof.  
23
- 24 49. A process in accordance with Claim 46 wherein the  
25 polyalkyl aromatic hydrocarbon is dialkylbenzene.  
26
- 27 50. A process in accordance with Claim 28 which is an  
28 oligomerization process comprising contacting an olefin  
29 feed under oligomerization conditions with the zeolite  
30 of Claim 1.  
31  
32  
33  
34

-64-

- 01 51. A process in accordance with Claim 28 which is a  
02 catalytic reforming process comprising contacting a  
03 hydrocarbonaceous feedstream under catalytic reforming  
04 conditions with the zeolite of Claim 1.  
05
- 06 52. A process in accordance with Claim 28 which is a  
07 process for preparing a product having an increased  
08 aromatic content comprising:  
09
- 10 (a) contacting a hydrocarbonaceous feed, which  
11 comprises normal and slightly branched  
12 hydrocarbons having a boiling range above about  
13 40°C and less than about 200°C under aromatic  
14 conversion conditions with the zeolite of Claim 1  
15 wherein said zeolite is substantially free of  
16 acidity; and  
17
- 18 (b) recovering an aromatic-containing effluent.  
19
- 20 53. A process in accordance with Claim 28 for the catalytic  
21 conversion of lower aliphatic alcohols having 1 to 8  
22 carbon atoms to form gasoline boiling range  
23 hydrocarbons which comprises contacting the alcohols  
24 under converting conditions with a zeolite of Claim 1.  
25
- 26 54. The process of Claim 53 wherein the alcohol is  
27 methanol.  
28
- 29 55. The process in accordance with Claim 28 which is a  
30 process for converting a C<sub>2</sub>-C<sub>6</sub> olefin or paraffin  
31 feedstream to aromatic compounds comprising contacting  
32 the feed material under aromatic conversion conditions  
33 with a zeolite of Claim 1.  
34

# INTERNATIONAL SEARCH REPORT

International Application No. PCT/US91/00589

## I. CLASSIFICATION OF SUBJECT MATTER (If several classification symbols apply, indicate all) \*

According to International Patent Classification (IPC) or to both National Classification and IPC  
 IPC (5): B01J 29/04; C07C 45/34; C10G 11/05, 47/16  
 U.S. Cl.: 502/64; 208/46, 111, 120; 568/360; 423/277, 329

## II. FIELDS SEARCHED

Classification System	Minimum Documentation Searched ?	Classification Symbols
U.S.	502/64 208/46, 111, 120 568/260 and 423/277, 329	

Documentation Searched other than Minimum Documentation  
 to the Extent that such Documents are Included in the Fields Searched \*

## III. DOCUMENTS CONSIDERED TO BE RELEVANT \*

Category *	Citation of Document, <sup>11</sup> with indication, where appropriate, of the relevant passages <sup>12</sup>	Relevant to Claim No. <sup>13</sup>
A	US, A, 4,393,244 (BHADIRI ET AL), 12 July 1983, See entire document.	8-12, 19-27
A	US, A, 4,665,110 (ZONES), 12 May 1987, See entire document.	1-55
Y,P	US, A, 4,902,844 (ZONES ET AL) 20 February 1990, See entire document.	1-55
Y,P	US, A, 4,910,006 (ZONES, ET AL), 20 March 1990, See entire document.	1-55

\* Special categories of cited documents: <sup>10</sup>

"A" document defining the general state of the art which is not  
 considered to be of particular relevance

"E" earlier document but published on or after the international  
 filing date

"L" document which may throw doubts on priority claim(s) or  
 which is cited to establish the publication date of another  
 citation or other special reason (as specified)

"O" document referring to an oral disclosure, use, exhibition or  
 other means

"P" document published prior to the international filing date but  
 later than the priority date claimed

"T" later document published after the international filing date  
 or priority date and not in conflict with the application but  
 cited to understand the principle or theory underlying the  
 invention

"X" document of particular relevance; the claimed invention  
 cannot be considered novel or cannot be considered to  
 involve an inventive step

"Y" document of particular relevance; the claimed invention  
 cannot be considered to involve an inventive step when the  
 document is combined with one or more other such docu-  
 ments, such combination being obvious to a person skilled  
 in the art.

"A" document member of the same patent family
